BATCH 11

STUDENT RESULT SYSTEM

ABSTRACT

Student Result System is a user-friendly result management application developed using Object-Oriented Programming (OOP) concepts in C++. The main purpose of this project is to provide a simple and organized platform for storing student details, entering subject marks, calculating total marks and percentage, assigning grades, and displaying student results. In educational institutions, manually calculating and maintaining student results can be time-consuming and may lead to errors in calculations and record management. This application helps manage student academic information efficiently and provides an organized approach to result processing. The project makes practical use of important OOP concepts such as classes, objects, encapsulation, constructors, member functions, and modular programming. Different functionalities can be organized into suitable classes, making the program easier to understand, maintain, and modify. A menu-driven interface allows the user to perform operations such as adding student records, entering marks, calculating grades, displaying results, searching records, updating information, and deleting records. File handling can be used to store student records permanently and retrieve them whenever required. The project also demonstrates how student data and result calculations can be managed using object-oriented design and function modularization. Overall, Student Result System provides practical understanding of C++ programming, OOP principles, grade calculation, data management, file handling, and problem-solving by combining these concepts to develop a simple, reliable, reusable, and user-friendly application.
